### Abstract

A new species of *Limonium* from Namaqualand coast, South Africa is here described and named *L. dagmarae*. Shared morphological characters with related South African species place the new species within *L.* sect. *Circinaria*. Evidence is presented to segregate the new species from relatives based on discrete morphological and environmental characters. The holotype of the *L. dagmarae* is preserved at NBG.

**Key words:** *Afrolimon*, *Limonium* sect. *Circinaria*, species nova, strandveld, Succulent Karoo

### Introduction

Plumbaginaceae Juss. is a moderately-sized family in the Caryophyllales Bercht. & J.Presl and comprises 25–30 genera and 650–1000 species (Hernández-Ledesma *et al.* 2015, Christenhusz & Byng 2016). *Limonium* Miller (1754: n.p.) is the largest genus in the family with c. 350 species, which are mainly coastal and Mediterranean (Hernández-Ledesma *et al.* 2015: 353). A previously recognised genus within the subfamily Limonioideae Reveal is *Afrolimon* Linczewski (1979: 167), which included several African species. The species within *Afrolimon* have a history of taxonomic uncertainty, being previously included within *Statice* Linnaeus (1753: 174) by Boissier (1848) and Wright (1909) or *Limonium* by Bolus (1934), then all later grouped into *Afrolimon* by Linczewski (1979), and finally being included again as species of *Limonium* by Goldblatt & Manning (2000). *Afrolimon* has been considered morphologically distinct from *Limonium*, with the synapomorphies of a capitate stigma and expanded corolla limb. However, the independent status of *Afrolimon* was, for the first time, challenged by Lledó *et al.* (2005) who found that their sequences of *A. peregrinum* (Bergius 1767: 80) Linczewski (1979: 168) and *A. purpuratum* (Linnaeus 1767: 59) Linczewski (1979: 168) were embedded within a clade containing the European species. Malekmohammadi *et al.* (2017) later found that the position of *Afrolimon* was incongruently resolved as the sister to the sect. *Limonium* subclade in the plastid versus the sister to a lineage constituted by the sections *Nephrophyllum*, *Platyhymenium* and *Siphonocalyx* in the nrITS trees. In order to ensure the monophyly of section concepts, Malekmohammadi *et al.* (2017) placed ‘*Afrolimon*’ in its own section *Limonium* sect. *Circinaria* (Boiss.) Malekmohammadi. The latter section, typified *L. peregrinum* (P.J.Bergius) Dyer (1961: 490), also suggested that the isolated position of this clade points to a reticulation event that gave rise to this lineage prior to the diversification of the different sub-lineages. This is an interesting point that might have a support in the fact that (at least some) *Afrolimon* taxa readily hybridize, which has been used by horticulture (see below). There are currently about 20 *Limonium* species native to South Africa (Dyer 1963, Goldblatt & Manning 2000, Manning & Goldblatt 2012, Mucina & Snijman 2013), yet with many more taxa recognised and awaiting formal description (Mucina, pers. obs.).

This paper describes a new, so far overlooked *Limonium* species from the Namaqualand coast of South Africa and provides comparison with morphologically similar species occurring in the Cape region.

## Material and methods

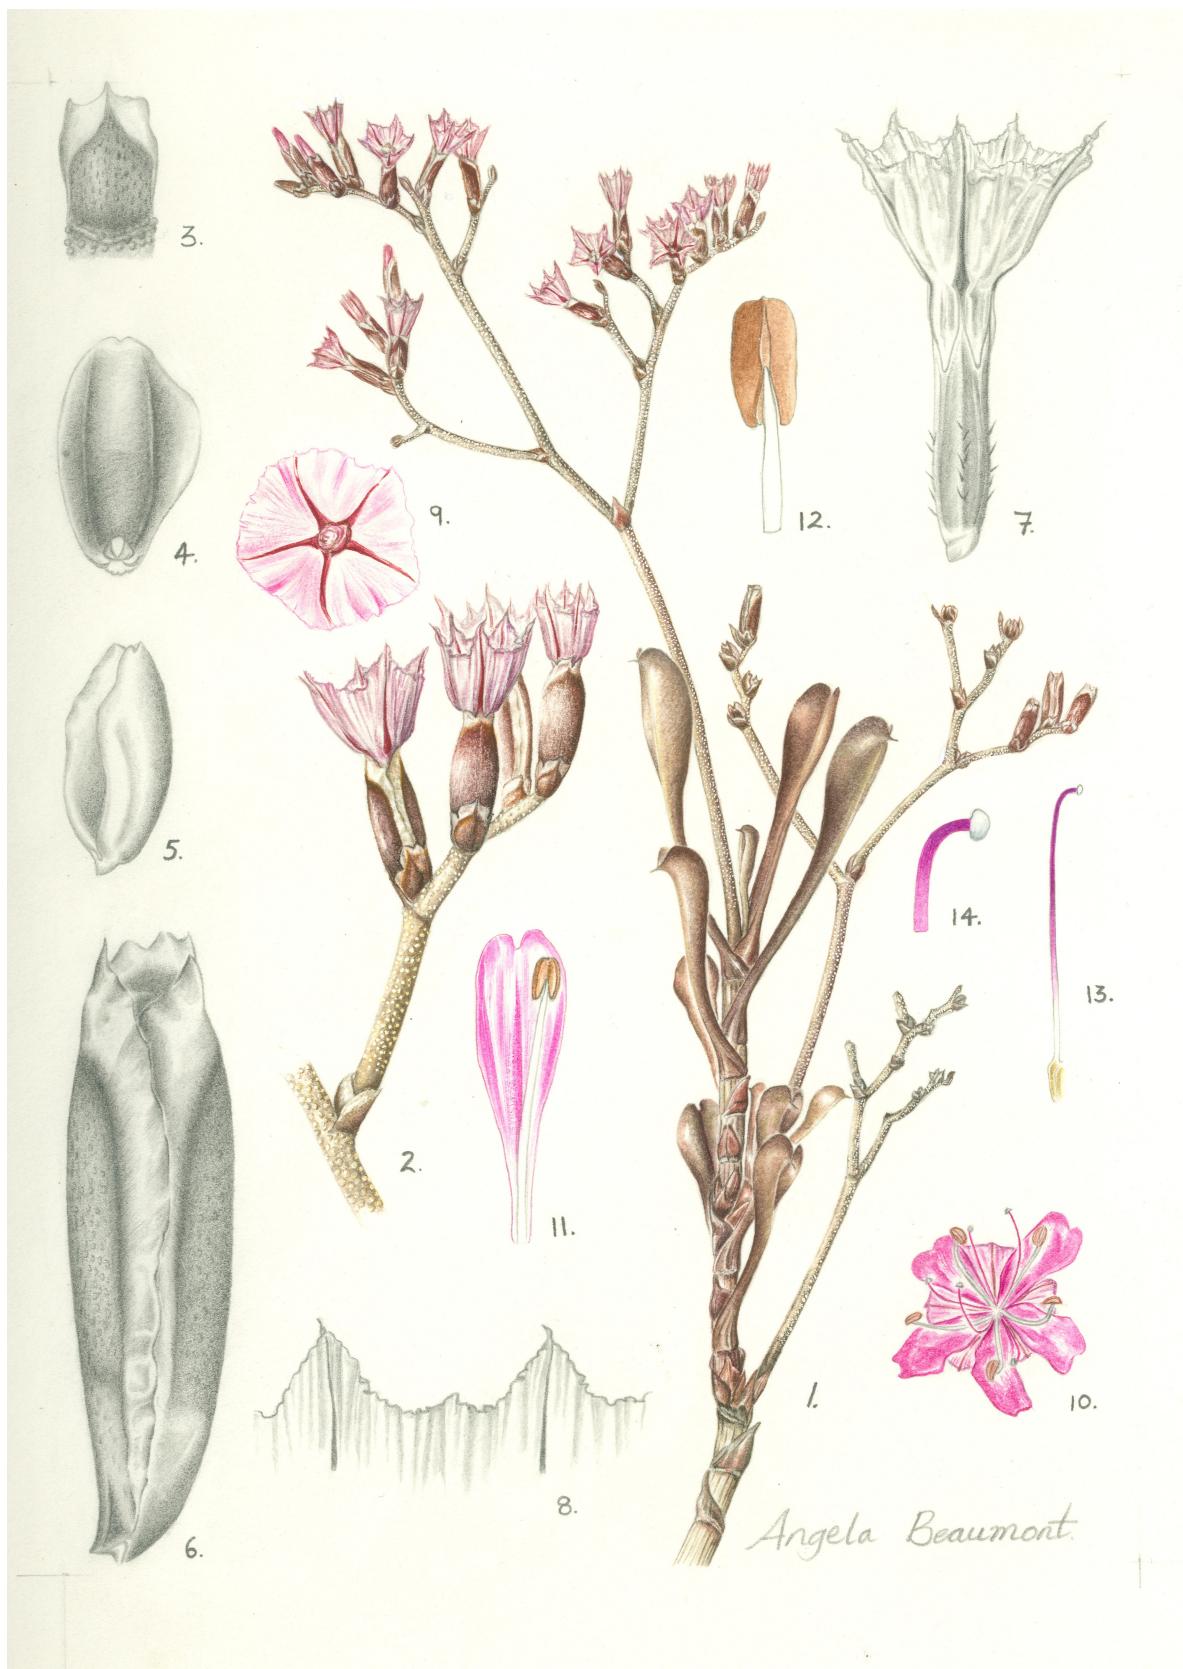

This study was based on the examination of freshly collected material, observations made in the field and herbarium specimens deposited at NBG (incl. NBG-SAM and NBG-STE), BOL, GRA, PRE and PRU (herbaria acronyms according to Thiers 2019+). The morphologically similar South African species *L. peregrinum*, *L. purpuratum* (L.) Bailey (1916: 158), and *L. longifolium* (Thunberg 1794: 54) Dyer (1961: 490) were also examined to compare with the new species (see Appendix 1 for a full list of specimens examined). A distribution map of all examined species was produced using georeferenced herbarium collections, and when necessary *a posteriori*, georeferenced approximations were obtained based on specimen label data and personal field observation occurrence notes.

## Results and discussion

The examination of specimens has led to the recognition of *Limonium dagmarae* Mucina sp. nov. (Figs. 1 & 2; see Taxonomy below), which has been earlier collected and commonly identified as *L. peregrinum*, as well as *L. longifolium* on few occasions (see Specimens Examined). Although *L. dagmarae* has not been mistaken for *L. purpuratum* in the past, we include the latter species in the comparison to clarify their relationship. Comparisons between these species and *L. dagmarae* are available in Tables 1 and 2. These four taxa are closely related, as shown unequivocally by molecular-phylogenetic analyses including *L. peregrinum* and *L. purpuratum* (Lledó *et al.* 2005). Beside striking difference in ecology (see Table 2 and the Habitat section below for more detail) and non-overlapping (at fine scale) distribution areas (Fig. 3), the main differences between the compared species are in habit and leaf characters such as length, number, indumentum (Fig. 4; Table 1). *Limonium dagmarae* shares the closest affinity to *L. peregrinum*, but they can be easily distinguished by the latter species having distinctly different leaves, which are shiny, significantly broader and grouped at the base of untidy spreading branches (Fig. 4C). *L. dagmarae* has very rough, narrower leaves with abaxial lamina densely covered with salt glands (Fig. 2). *Limonium longifolium* has a very different growth form, forming erect, bloomy-like lax shrubs and often very long leaves (when fresh) are invariably glaucous. Included also in the comparisons are specimens of *L. longifolium* that have been putatively classified *L. fergusoniae* L.Bolus (1934: 124). These are very low shrubs (below 20 cm) and have no direct resemblance with *L. dagmarae*. In growth-form, *L. dagmarae* is similar with *L. purpuratum*, though the latter species has smooth leaves and lacks the rough laminar surface of *L. dagmarae*. The strong affinity with *L. peregrinum*, *L. purpuratum* and *L. longifolium*, suggest that *L. dagmarae* belongs to the taxon initially described as *Statice* sect. *Circinaria* Boiss. (Boissier 1848) that served later (Linczevski 1979) as basis of description of the genus *Afrolimon*.

Our observations do not concur with the statement by Malekmohammadi *et al.* (2017) that these plants are subshrubs. This category is reserved for plants having (at maturity) young herbaceous (hence short-lived) branches while the base of the stem and the branches is woody. At maturity all species formerly classified as *Afrolimon* are shrubs; albeit the young branches are always herbaceous when they are formed, they are not shed in herbaceous stage, but become woody as they would mature (L. Mucina, pers. obs.). Neither do we concur with the latter authors' statement that the *Afrolimon* species are 'restricted to littoral and non-littoral salt-marshes'. None of the described and undescribed species of *Limonium* sect. *Circinaria* are obligate halophytes.

In southern Africa (defined here as the African subcontinent south of the rivers Cunene and Zambezi), the native *Limonium* comprise, besides those formerly classified as *Afrolimon*, a large number of herbaceous taxa (Dyer 1963; L. Mucina, unpublished data), morphologically reminiscent of species commonly occurring around the Mediterranean, and indeed two of those (*Limonium scabrum* Kuntze (1891: 396) and *Limonium kraussianum* Kuntze (1891: 396)) fall within a 'Mediterranean clade B3', corresponding to *Limonium* sect. *Limonium* subsect. *Steirocladae* (Koutroumpa *et al.* 2018, Fig. 3). Another South African herbaceous species, *L. anthericoides*, (Schlechter 1897: 450) Dyer (1932: 155) was shown (Koutroumpa *et al.* 2018) to be sister to the Macaronesian *L. sect. Pteroclados* (Boiss.) Bokhari (= *L. subg. Pteroclados* sensu Lledó *et al.* 2005). *Limonium dagmarae* is distinctly different from all southern African herbaceous *Limonium* representatives.

**FIGURE 1.** Drawing (original) of *Limonium dagmarae* (voucher L. Mucina 250901/25M2, Doringbaai): 1. Stem with flowering branches and leaves (leaf scars are visible in the lower part of the stem), 2. side branch showing post-anthesis calyces, 3. outer supportive bract (supporting the flower), 4. dorsal view of the middle supportive bract, 5. side view of the middle supportive bract, 6. inner (most conspicuous) supportive bract, 7. side view of the calyx tube, 8. shape of the top calyx lobes (calyx rim), 9. top-down view of the calyx, 10. corolla with anthers, 11. corolla petal with anther basally attached, 12. anther, 13. stigma, 14. detail of the stigma. The size of the branch (picture 1. serves as the scale; the branch is c. 30 cm long). Artist: Angela Beaumont.

**FIGURE 2.** *Limonium dagmarae* in situ (the southernmost population of the species, origin of the voucher *L. Mucina* 250901/25M2). A: overall habit (semiglobose-shaped low shrub); B: view of a branch that finished flowering not long ago (the papery calyces are still light pink and brownish ribs prominent; also showing the sparse leafing of the branch); C: fully developed flower, flanked by several calyces which perigone already withered and several buds prepared to flower. D: habitat of *L. dagmarae* – loamy-sandy strandveld scrub, with associated succulent shrubs (Aizoaceae and *Euphorbia decussata* E.Mey. and *E. mauritanica* L.). All photos L. Mucina.

**TABLE 1.** Comparison of some basic morphological traits able to assist field identification of four putatively related *Limonium* species of the sect. *Circinaria*.

	<i>L. dagmarae</i>	<i>L. peregrinum</i>	<i>L. purpuratum</i>	<i>L. longifolium</i>
Life-form	low to mid-tall shrub	low shrub	low to mid-tall shrub	low to mid-tall shrub
Overall appearance	rounded semiglobose	broadly lax	broadly semiglobose	broomy lax
Shape of the terminal flowering branches	arching	arching	erect or slightly arching	erect
Leaf shape	narrowly cuneate with lamina tapering into petiole-like base; when dry, lamina folded and with the leaf tip flexed backwards	broadly cuneate or obovate with lamina tapering into petiole-like base; when dry, lamina remains flat	obovate-cuneate, oblanceolate to oblinear-lanceolate with lamina smoothly grading into broad petiole; when dry, lamina folded and slightly flexed backwards	linear-oblanceolate and sometimes narrowly spatulate, with lamina inconspicuously grading into broad petiole
Leaf lamina length <sup>1</sup>	3–5 cm	3–8 cm	8–18 cm	up to 30 cm
Leaf surface	both surfaces rough; especially the abaxial side of lamina densely covered with salt glands; reddish-brown when both fresh and dry	adaxial surface often shiny (in situ); abaxial surface rough and pitted; shiny green when fresh and dark green when dry	both surfaces smooth with only faint pitting; dark green when fresh and dark grey when dry	both surfaces smooth or very minutely scabrid; glaucous when fresh and dark grey when dry
No of leaves per leaf tuft <sup>1</sup>	5–15	8–20 <sup>3</sup>	5–7	6–9
Dry calyx colour <sup>2</sup>	light pink to white	deep to light pink	light pink	light brown
Flower colour	light pink	deep pink	light pink	white

<sup>1</sup>counted on 10 randomly chosen voucher specimens

<sup>2</sup>the dry calyx colour is dominated by the colour of the calyx veins

<sup>3</sup>the low number of leaves refers to young yet fertile specimens

**TABLE 2.** Summary of ecology of four putatively related species of *Limonium* sect. *Circinaria*. The biome and vegetation-typological terminology follows Mucina & Rutherford (2006) and Mucina (2019). The nutrient status of soils as well as texture and colour source data from field observations (L. Mucina, unpubl. data).

	<i>L. dagmarae</i>	<i>L. peregrinum</i>	<i>L. purpuratum</i>	<i>L. longifolium</i>
Soil texture; colour	Ca- and P-rich; loamy-sandy; red	Ca- and P-rich; sandy; yellow	nutrient-poor; sandy; white	nutrient-poor; sandy; white
Soil nutrient-status	high	high	low	low
Salt-spray influence	rare (impacting only few coastal cliff populations)	strong and regular	none	none
Vegetation type	tall dry strandveld	low strandveld scrub	restio-dominated fynbos	restio-dominated fynbos
Biome	Succulent Karro, partly Fynbos (dry dune fynbos scrub) and coastal azonal vegetation	Fynbos (Strandveld)	Fynbos (Sand Fynbos)	Fynbos (Sand Fynbos)

## Taxonomy

### *Limonium dagmarae* Mucina sp. nov. (Figs. 1 and 2)

**Type:**—**SOUTH AFRICA. Western Cape:** Bitterfontein District, Farm Katdoringvlei, Ruitersvlei, approx. 2 km WSW of farmhouse, elev. 180 m, 25 October 1988, L.W. Powrie 742 (NBG-STE!, sub *L. 'perigrinum'*, recte: *L. peregrinum*).

**Synonym:**—‘*Limonium* sp. A (= *Limonium dagmarae* Mucina ms)’ in Mucina & Snijman, Plants of the Greater Cape Floristic Region. 2: The Extra Cape Flora, p. 439; 2013. (nomen nudum, Art. 38 in ICN, Turland *et al.* 2018).

**Description:**—*Shrub* up to 60 cm tall when mature, ramified, with woody tap-root. *Stems* 5–30 cm long, multiple, originating from root head, ascending and becoming broadly arched; colour green-copper when young, older mainly copper-coloured; glabrous and smooth; petioles of senesced leaves persistent; densely branched in the upper half or third. Branches 5–15 cm long, curved, dense, mostly unilaterally ramified; copper-coloured; glabrous and wrinkled. *Leaves* 10–40 mm long (including the petiole) and 5–10 mm wide, obovate or oblanceolate and typically channeled, finely scabrous, alternate, occurring solitary along the stem and branches, located mainly in the lower half or lowest third of the stems/branches; colour coppery and green-coppery; apex rounded to broad acute; petiole c. 5 mm long, partly channeled. *Spikes* 10–30 mm long, straight or slightly curved, terminating at same level. *Spikelets* 12–15 mm long, single-flowered, loosely arranged on spike. *Outer bract* 2.6–2.8 mm long and 2.0–2.5 mm wide, broadly triangulate-ovate; central part of bract fleshy, triangular, with tip reaching as far as the margin; bract margin narrowly white-membranous, serrate; apex acute. *Middle bract* 2.9–3.1 mm long and 1.8–2.0 mm wide, broadly-elliptic to obovate; central part of bract fleshy, bifurcated, with two unequally long tips, 2.5–2.8 mm long; bract margin narrowly white-membranous, 0.2–0.5 mm long at apices, serrate; apices rounded. *Inner bract* 8.5–9.0 mm long and 6.3–7.0 mm wide, broadly-elliptic to broadly obovate, encircling calyx tube; central part fleshy, 8.3–8.6 mm long and 4.9–5.3 mm wide, oblong-elliptic, apex with one triangular tip, 0.1–0.2 mm long reaching more or less to the margin; margin white-membranous, 1.2–2.2 mm wide; apex finely serrate, membranous to 0.5–1.0 mm long. *Calyx* broadly funneliform (infundiform), 5.0–5.5 mm long and exerted beyond the inner bract by 2.0–3.0 mm; calyx tube 6.8–7.0 mm long with five fleshy ribs terminating c. 1 mm below the margin, lower half covered by short, bristly hairs. *Corolla* light pink. *Petals* approx. 3–5 mm long and c. 2–3 mm broad, fused at the base and forming short corolla funnel, wedge-shaped, rounded on the upper end. *Stamens* with versatile anthers divided halfway. *Ovary* 5-winged; styles 5, free. *Stigma* capitate.

**Phenology:**—Flowering has been observed and recorded from August to November, which is typical of the warm-temperate, mediterranean-type climate of the Cape, characterised by wet and cool winter and spring. Interestingly, most of the *Limonium* species so far described from South Africa (and not belonging to the *Limonium* sect. *Circinaria*) are summer-flowering. The flower corollas are short-lasting (only few days) and appear in successive cohorts during the flowering time.

**Distribution:**—Endemic to the Namaqualand coast, between Doringbaai, Western Cape and Kleinzee, Northern Cape Province (Fig. 3).

**Habitat:**—*Limonium dagmarae* is typically found in open arid strandveld scrub, dominated by succulent subshrubs of the genera *Ruschia* Schwantes (1926: 234), *Drosanthemum* Swantes (1927: 14, 29), *Vanzylia* L.Bolus (1927: 262) (all Aizoaceae Martinov), *Euphorbia* L. (Euphorbiaceae Juss.) and *Caroxylon* Thunb. (1782: 240–241) (Chenopodiaceae Vent.). In the southern section of its distribution area (Brandsebaai near Vredendal and southwards) it is confined to SKs 7 Namaqualand Strandveld (terminology follows Mucina & Rutherford 2006), while further north it is also found in SKs 8 Namaqualand Coastal Duneveld. Both SKs 7 and 8 are part of the Succulent Karoo Biome. Coastal populations characterised by dwarfed habitus are found in AZd 2 Namaqualand Seashore Vegetation (near Hondeklipbaai) and AZd 3 Cape Seashore Vegetation (near Doringbaai). Few populations found east of Hondeklipbaai occur in arid FFd 1 Namaqualand Sand Fynbos (part of the Fynbos Biome).

Ecologically, *L. dagmarae* is one of the most arid (semi-desert) elements within *Limonium* sect. *Circinaria*. Of three other species of this section morphologically somewhat similar with *L. dagmarae*, ecologically most similar is *L. peregrinum* which occurs within Fynbos Biome realm while *L. dagmarae* is linked mainly to Succulent Karoo Biome (Table 2). When comparing the latter two taxa, *L. dagmarae* occurs only rarely under direct salt-spray influence (on coastal cliffs or shell beds) – here in a creeping, poorly developed form, while *L. peregrinum* is typical of stabilised coastal dunes and calcareous outcrops associated with the coastal dune systems.

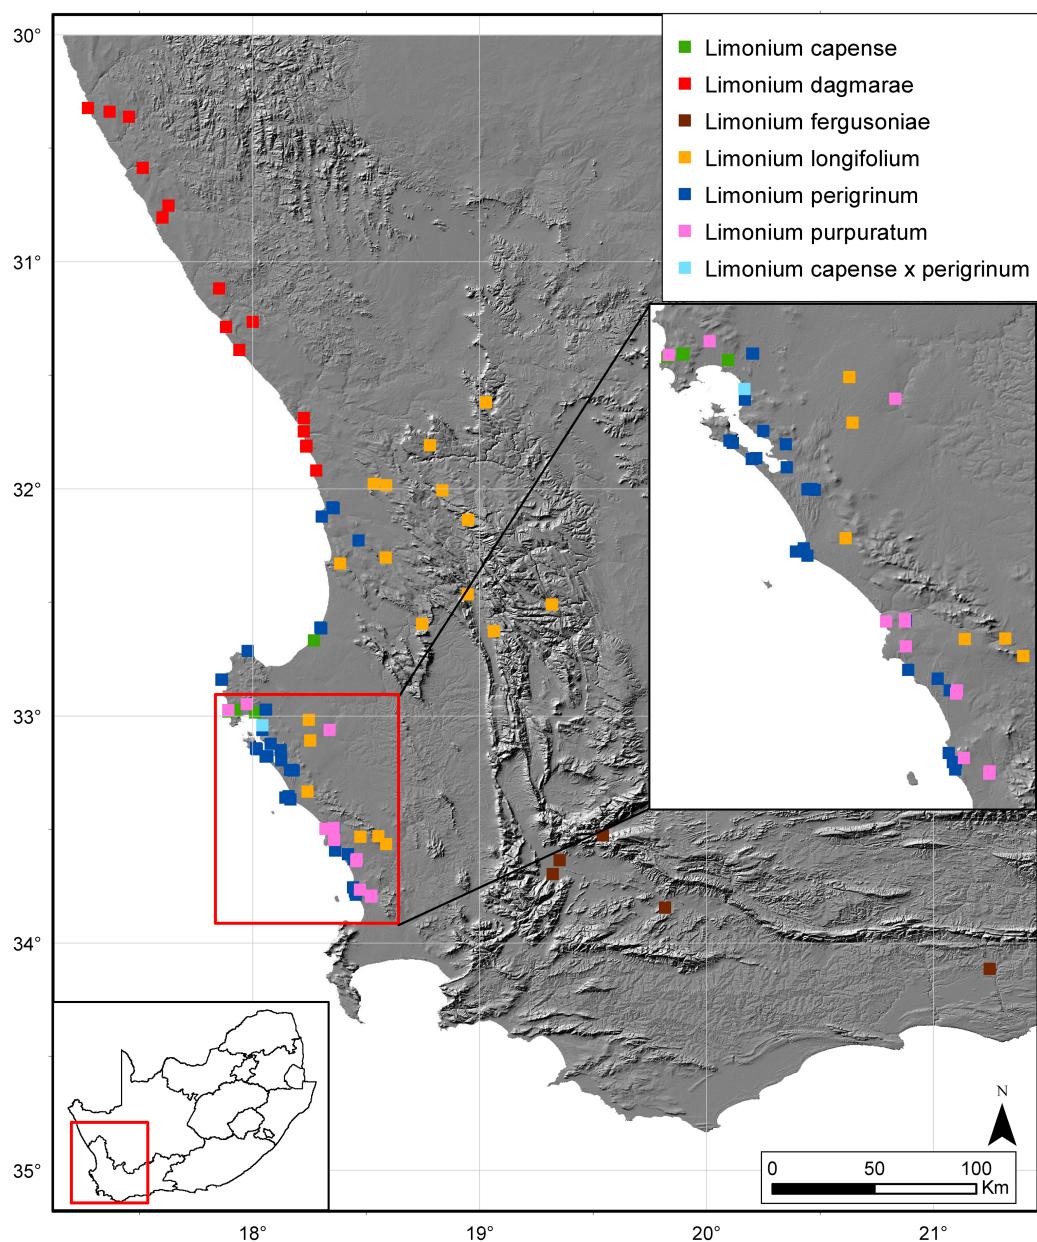

Unlike *L. peregrinum*, *L. purpuratum* and *L. longifolium* (all occurring on sandy soils), *L. dagmarae* prefers stabilised red sandy-loamy soils.

**Horticultural significance:**—Many *Limonium* species have been taken subject of horticultural research (e.g. European Union 2002, Antonetti 2012) into cultivation and have proven to be popular garden ornamentals, mainly because of persistent conspicuous colourful calyces (Mediterranean *L. sinuatum* (L.) Mill., making it a wide spread popular ‘paper-flower plant, colour combinations involving flowers and calyces as well as showy leaves (Canarian *L. perezii* (Stapf) F.T.Hubb.), and even showy leaf rosettes (Sicilian *L. hyblaeum* Brullo). As an unwanted side effect of the popularity of those taxa, one has to acknowledge that some became invasive (*L. sinuatum* in South Africa, *L. hyblaeum* in Western Australia) and some might possess invasive potential (*L. perezii*). Of taxa similar with *L. dagmarae*, *L. peregrinum* became popular as cut plant (Reynten *et al.* 2011), or garden ornamental (L. Mucina, pers. obs., Chile, Zapallar).

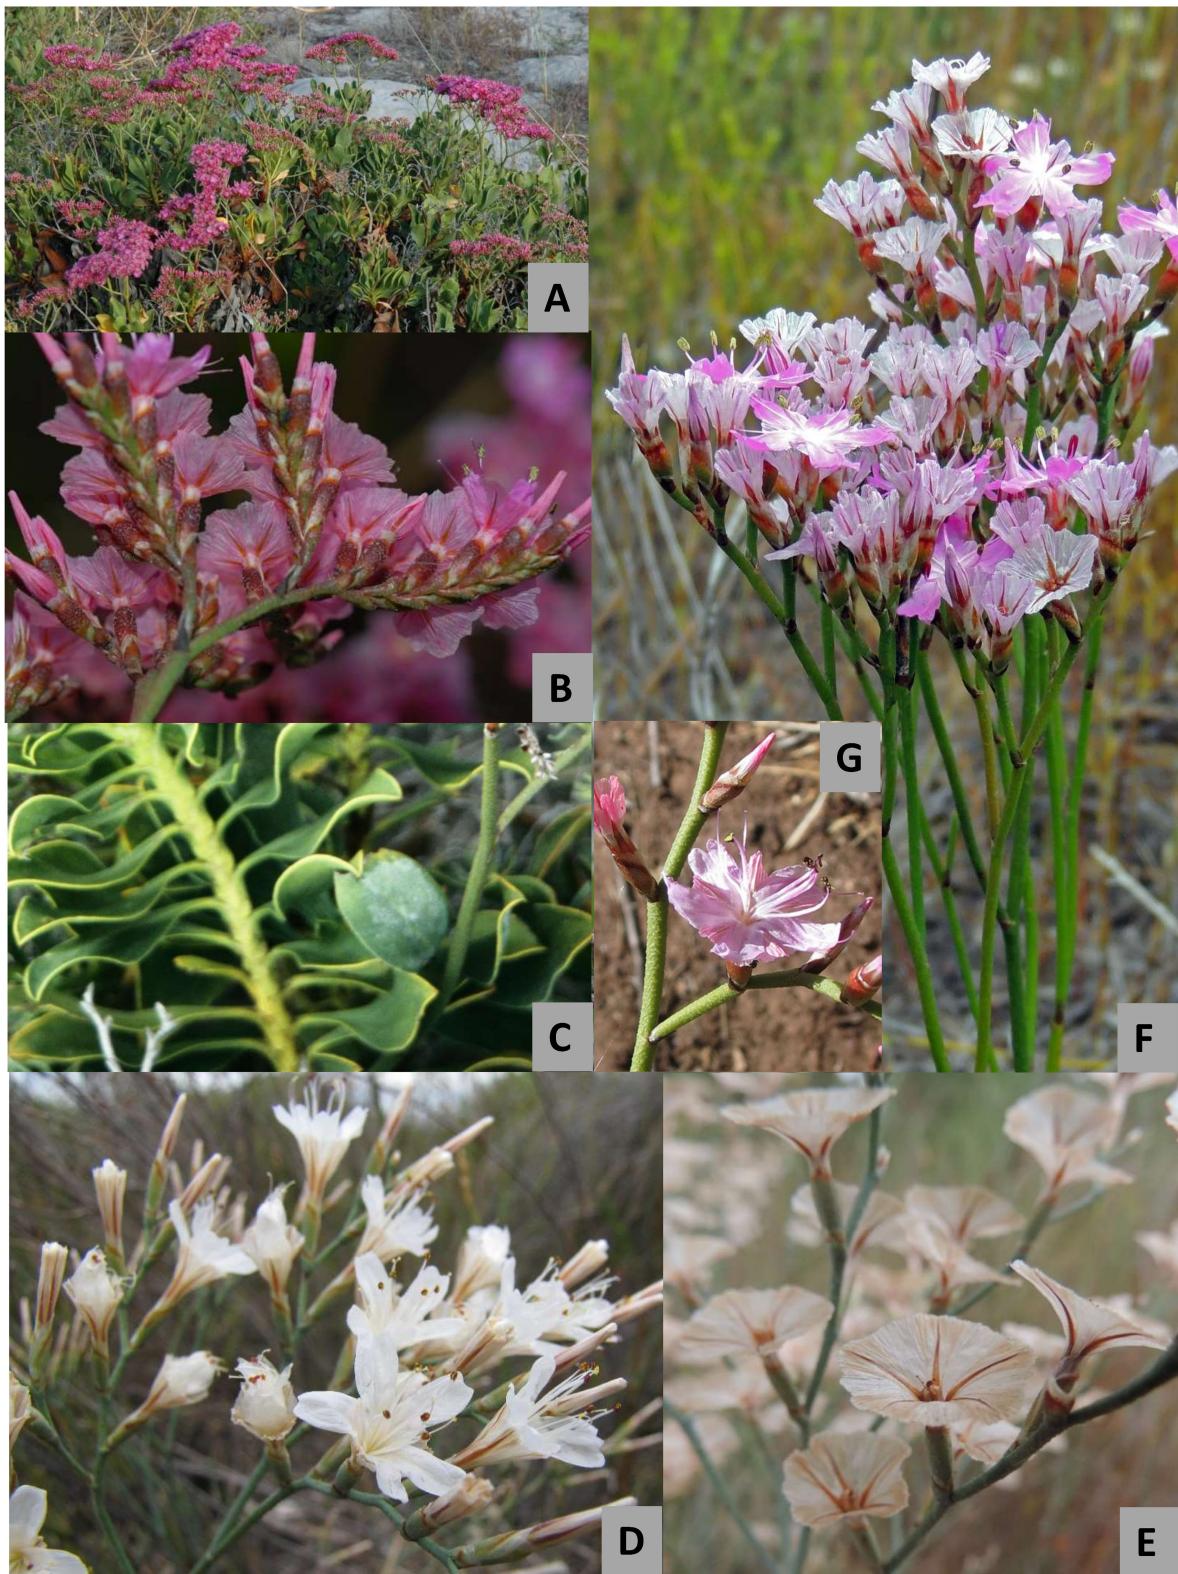

*Limonium peregrinum* and *L. purpuratum* became a subject of breeding (Morgan *et al.* 1995, 1998, 2001, Burge *et al.* 1998, Seelye *et al.* 2000) in New Zealand. *Limonium dagmarae* is similarly showy both in anthesis (pink splashes of flowers and bright-coloured calyces) and in post-anthesis when temporary pink calyces persist for a while just to be replaced gradually by dense patches of dry white ones (Fig. 2) extending the visual delight further. Since the close relative *L. peregrinum* apparently is easy to cultivate, one can assume that the water-wise *L. dagmarae* might eventually find a way to cultivation (see also Reinten *et al.* 2011).

**Conservation assessment:**—Following the criteria of the IUCN Standards and Petitions Subcommittee (2017), *Limonium dagmarae* is Endangered: B1a,b(I,ii,iii,iv); C2a(ii). *L. dagmarae* occurs in region spanning 96 latitudinal minutes (c. 205 km of aerial distance between the northernmost and southernmost locality) and within this span it occurs in a 5–10 km broad belt. Their local populations of the species count several tens of individuals. So far, the extensive population occurs on private land (lightly grazed) north of settlement (Doringbaai near Vredendal, Western Cape Province). It is potentially endangered by further settlement development.

Ex situ conservation using tissue cultures, as applied in the case of *L. sinensis* (Dam *et al.* 2010) or being developed in Bulgaria (Kaninski *et al.* 2012), seems like a feasible option to enhance survival of the species.

**FIGURE 3.** Distribution of putatively related species (and one hybrid) of *Limonium* sect. *Circinaria* in the SW Western Cape and Namaqualand (South Africa).

**FIGURE 4.** Three most similar (with *Limonium dagmarae*) *Limonium* species (all photographed on the West Coast, Western Cape Province of South Africa). A: *L. peregrinum*, overall habitus, coastal dunes, Langebaan; B: *L. peregrinum*, arrangement of the terminal flowering branches, view from the abaxial side, Paternoster; C: *L. peregrinum*, typical dense leafing on a branch, Langebaan; D: *L. longifolium*, terminal inflorescence with typically white flowers, Elandsfontein; E: *L. longifolium*: post-flowering terminal branch with broadly opened papery calyces, note also the grey-coloured surface of the branches, Atlantis ; F: *L. purpuratum*: typical tall broomy habitus in young specimens; G: *L. purpuratum*, detail of a fully developed flower and bud (above the flower), Jacobsbaai. Photos: A, B: G. López; C: L. Mucina; D: N. Helme (iSpot); E (iSpot), F: J. van der Merwe; G: K. Claassens (iSpot).

**Etymology:**—Named in honour of Dagmar Mucina, the life partner and wife of the first author, in recognition of her indispensable support and her shared passion for the flora of Namaqualand.

Wooley-Dod* 2123 (PRE!, sub *L. longifolium*); [Namaqualand], Northwestern Cape, Groenbosvlei, elev. 400 ft, 8 December 1980, *P.M. van der Westhuisen* 206/80 (NBG-STE!, sub *L. 'perigrinum'*; CPA/KPA Nature Conservation Herbarium!, sub *L. 'perigrinum'*); Namaqualand, Sandveld, [Koingnaas], Zoutpan 471, on road from De Riet to Heidens [Haidons], 17 August 1993, *A. Le Roux* 4503 (CPA/KPA Nature Conservation Herbarium!, sub *L. longifolium*); Namaqualand, Bitterrivier, Langberg, on gravelly foothills, 2 November 1963, *H.C. Taylor* 5516 (NBG-STE!, sub *L. longifolium*). Imprecise locality: [Cape], *Ecklon & Zeyher* 70.10 (NBG-SAM 41399!, sub *S. tetragona*, *S. rosea*, *L. peregrinum*).

## Acknowledgements

We thank D. Gwynne-Evans, N. Helme, K. Claassens, G. López, J.C. Manning, L.W. Powrie and J. van der Merwe for providing some photos and sharing locality data. Curators of NBG, BOL, PRE, GRA and CPA/KPA Nature Conservation Herbarium granted permission to access the collections of their herbaria; D. Gwynne-Evans A. le Roux kindly provided access to their private collections. P. Winter helped with photos of voucher specimens.

A. Beaumont has drawn the plate of the new species and P. Macintyre helped to prepare the distribution map. Cape Nature, Northern Cape Nature Conservation Service and South African National Parks kindly issued permits to collect plants in the field.
